Efficient Sustainable Logistics

*An Open Innovation Initiative*

*4<sup>th</sup> International Physical Internet Conference*

# **Towards Hyperconnected Distribution: the Retail Supply Chain Reengineering**

**Yesmine Rouis**

Tunisia Polytechnic School, University of Carthage, Tunis, Tunisia

**Walid Klibi**

KEDGE Business School, Bordeaux, France

**Benoit Montreuil**

Coca-Cola Chair in Material Handling and Distribution

Physical Internet Center, ISYE, Georgia Tech, Atlanta, USA

## **Presentation plan**

- **Motivations and Business case challenges**
- **The current distribution system of the retailer company**
- **Exploring several reengineering scenarios**
- **Optimization-based Results**
- **Conclusion & Future work**

## Motivations : Omnichannel Business & City Logistics

The Omnichannel Business seeks to provide the customers with a seamless shopping experience, allowing them to order **anytime from anywhere**, in person or through digital devices and be delivered at their **preferred time and location**.

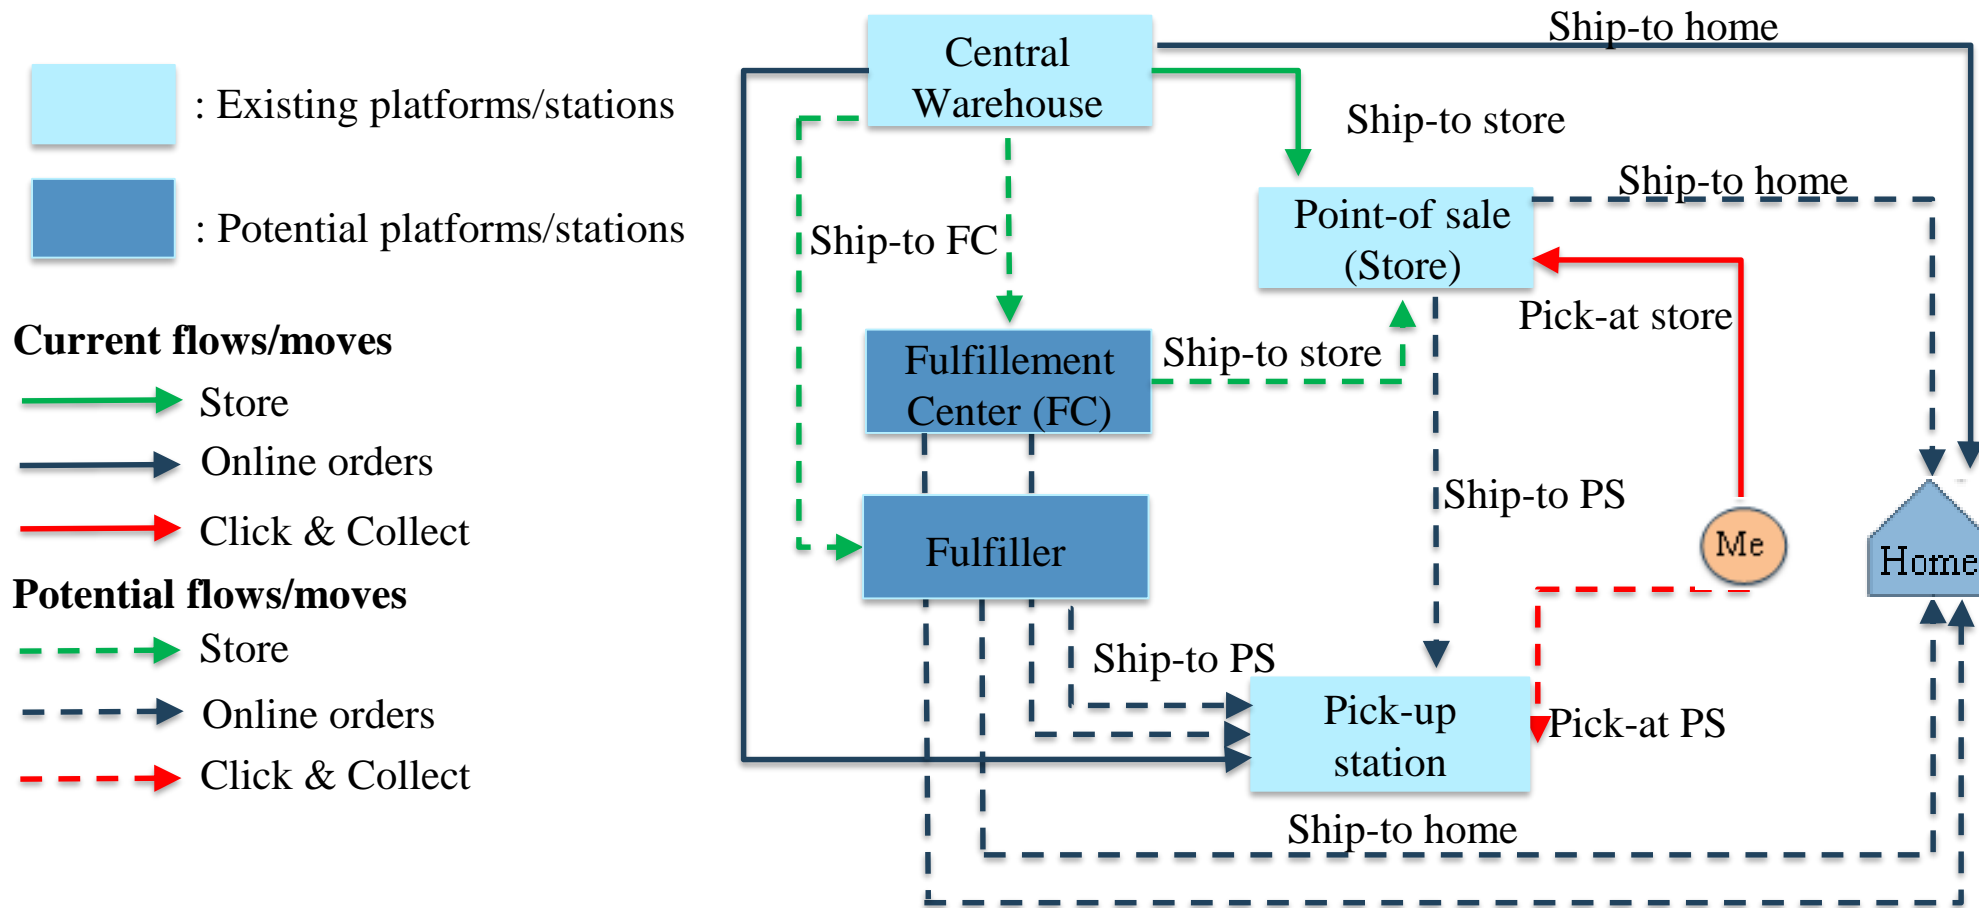

**City logistics** aims to **minimize** the **negative impact of freight-vehicle** movements on city-living conditions and to reduce the number of **empty vehicles** getting in, through and out of the city. It also seeks to improve **last-mile delivery management** and pre-position deployment of goods in cities.

# A Generic Vision of OmniChannel Distribution in the City

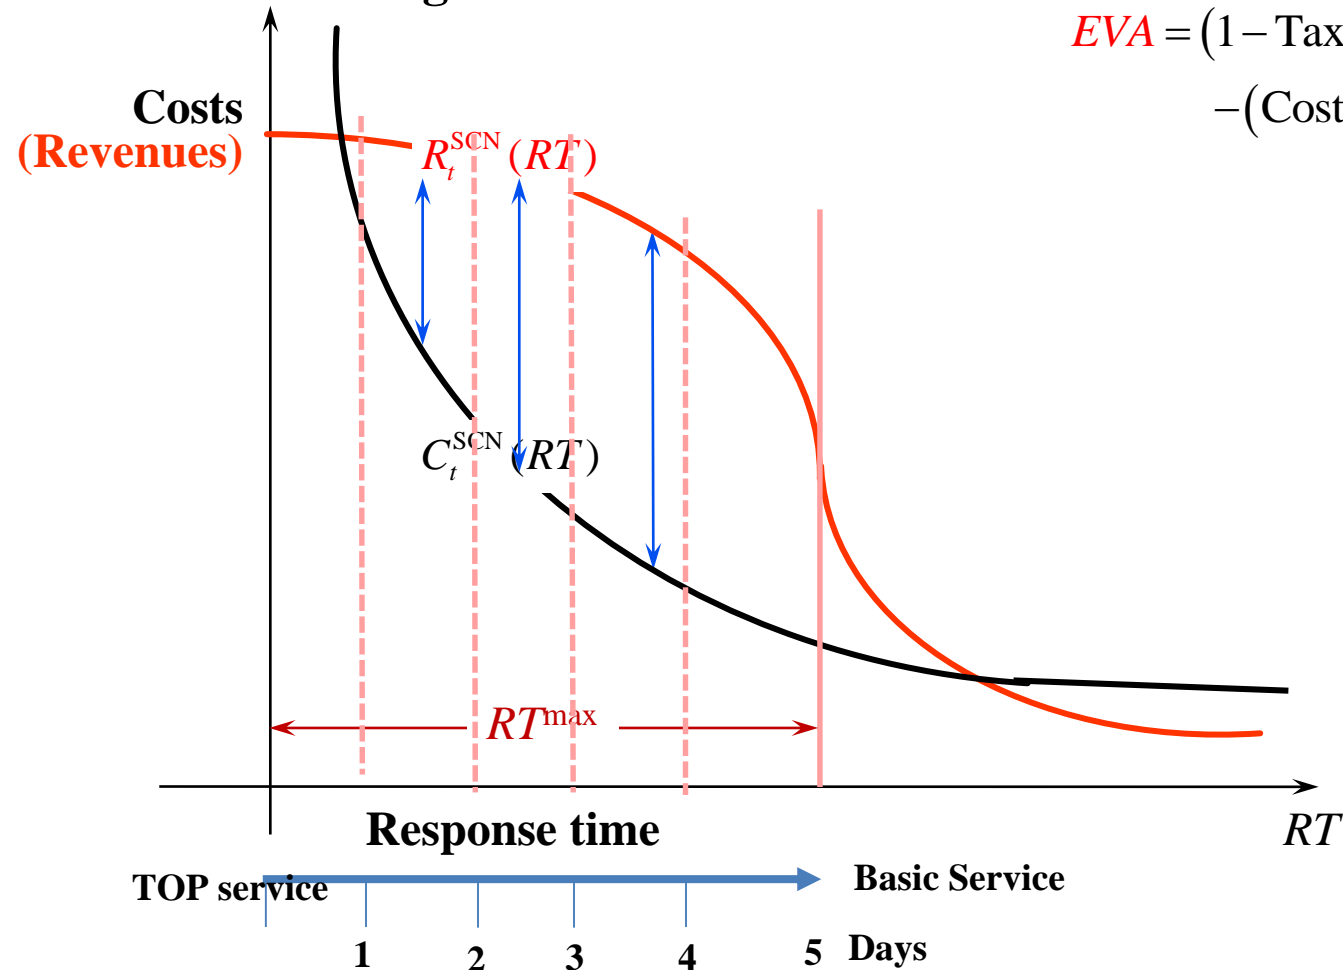

Adapted from Montreuil (2016)

# The need of a Hyperconnected Distribution Strategy

## ➤ Distribution Network Design drives Revenues

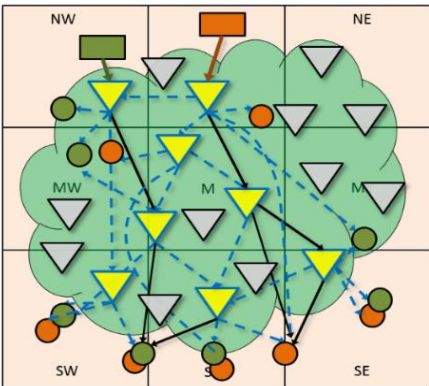

$$EVA = (1 - \text{Tax rate}) \times (\text{Revenues} - \text{Expenses}) - (\text{Cost of capital} \times \text{Capital employed})$$

## The need of a Hyperconnected Distribution Strategy

Exploiting **Physical Internet** and **interconnection in B2C goods deployment, pickup and delivery** is expected to create potential for drastic **fulfillment online orders process, profitability** and **ecological** performance improvements.

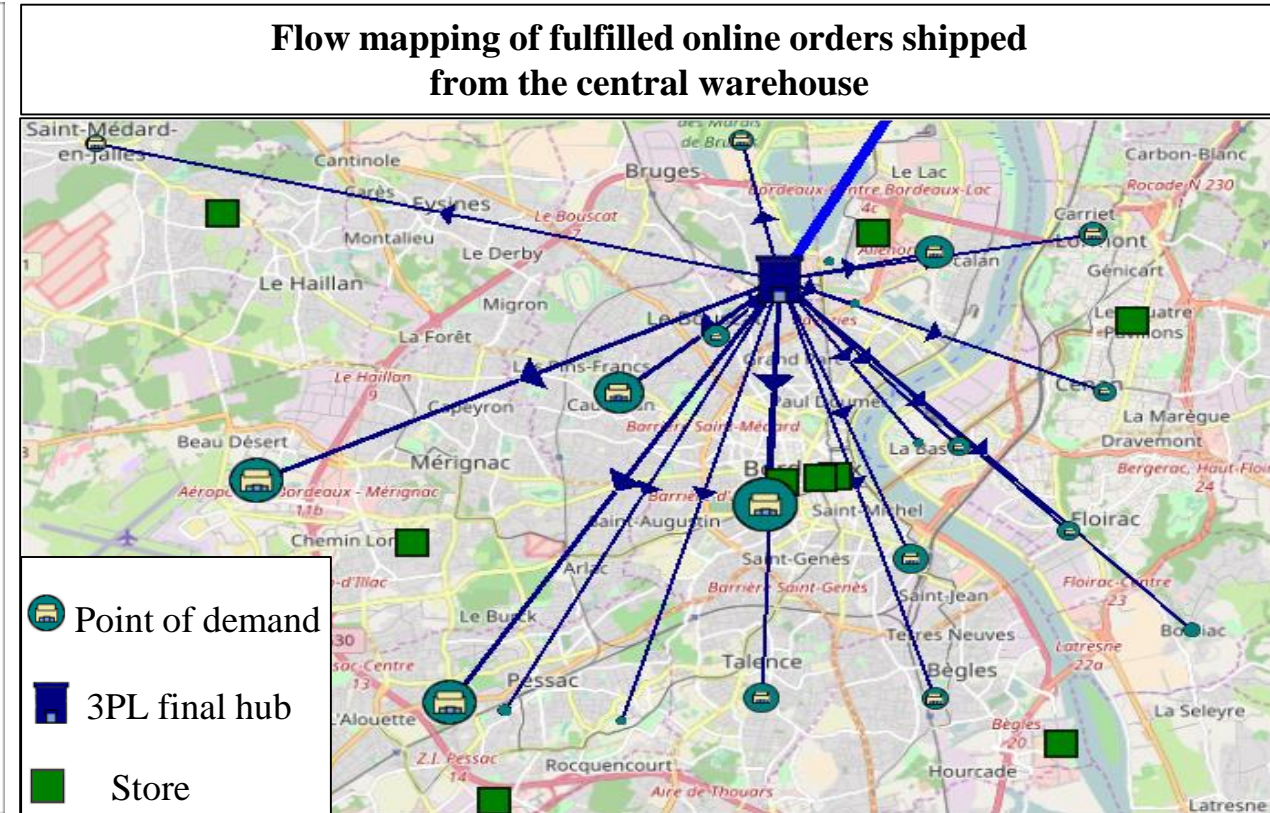

*Hyperconnected  
distribution web*

### ➤ **Distribution Web Strategy drives Revenues**

- Mid-term Planning Horizon (1 to 2 years)
- Design a flexible distribution schema (configuration & contracts).
- Own/rent/share/exploit a distribution web
- Offers are modulated by product-market (Prime response time)
- Plan to deploy flows dynamically (a variable mission for each DC)

## Overview on the current Distribution system

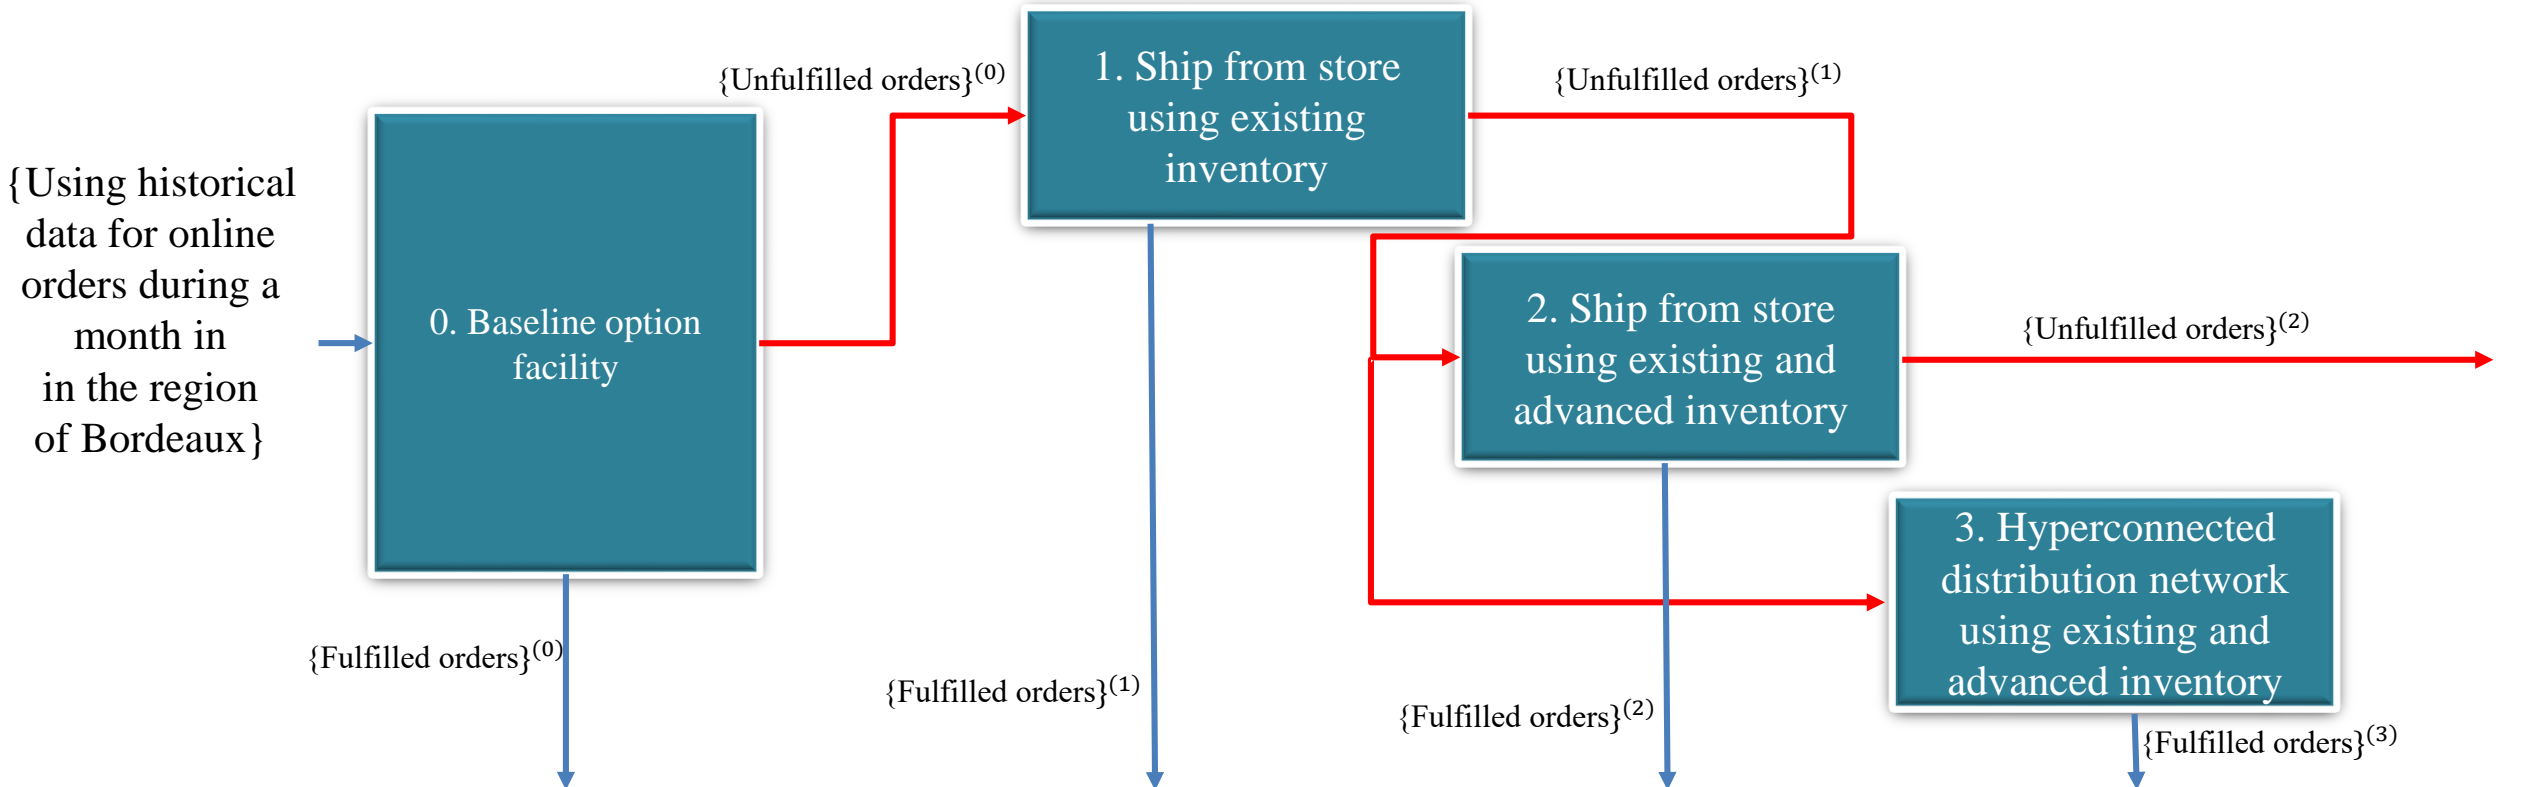

- 921 online orders / month
- 653 clients
- 9 stores

## Methodology

	Baseline	Scenario 1	Scenario 2	Scenario 3
<b>Percentage of fulfilled orders</b>	{Fulfilled orders} <sup>(0)</sup>	{Fulfilled orders} <sup>(0)</sup> ∪ {Fulfilled orders} <sup>(1)</sup>	{Fulfilled orders} <sup>(0)</sup> ∪ {Fulfilled orders} <sup>(1)</sup> ∪ {Fulfilled orders} <sup>(2)</sup>	{Fulfilled orders} <sup>(0)</sup> ∪ {Fulfilled orders} <sup>(1)</sup> ∪ {Fulfilled orders} <sup>(3)</sup>

## Distribution design models

### Scenario 1: Ship from store using existing inventory

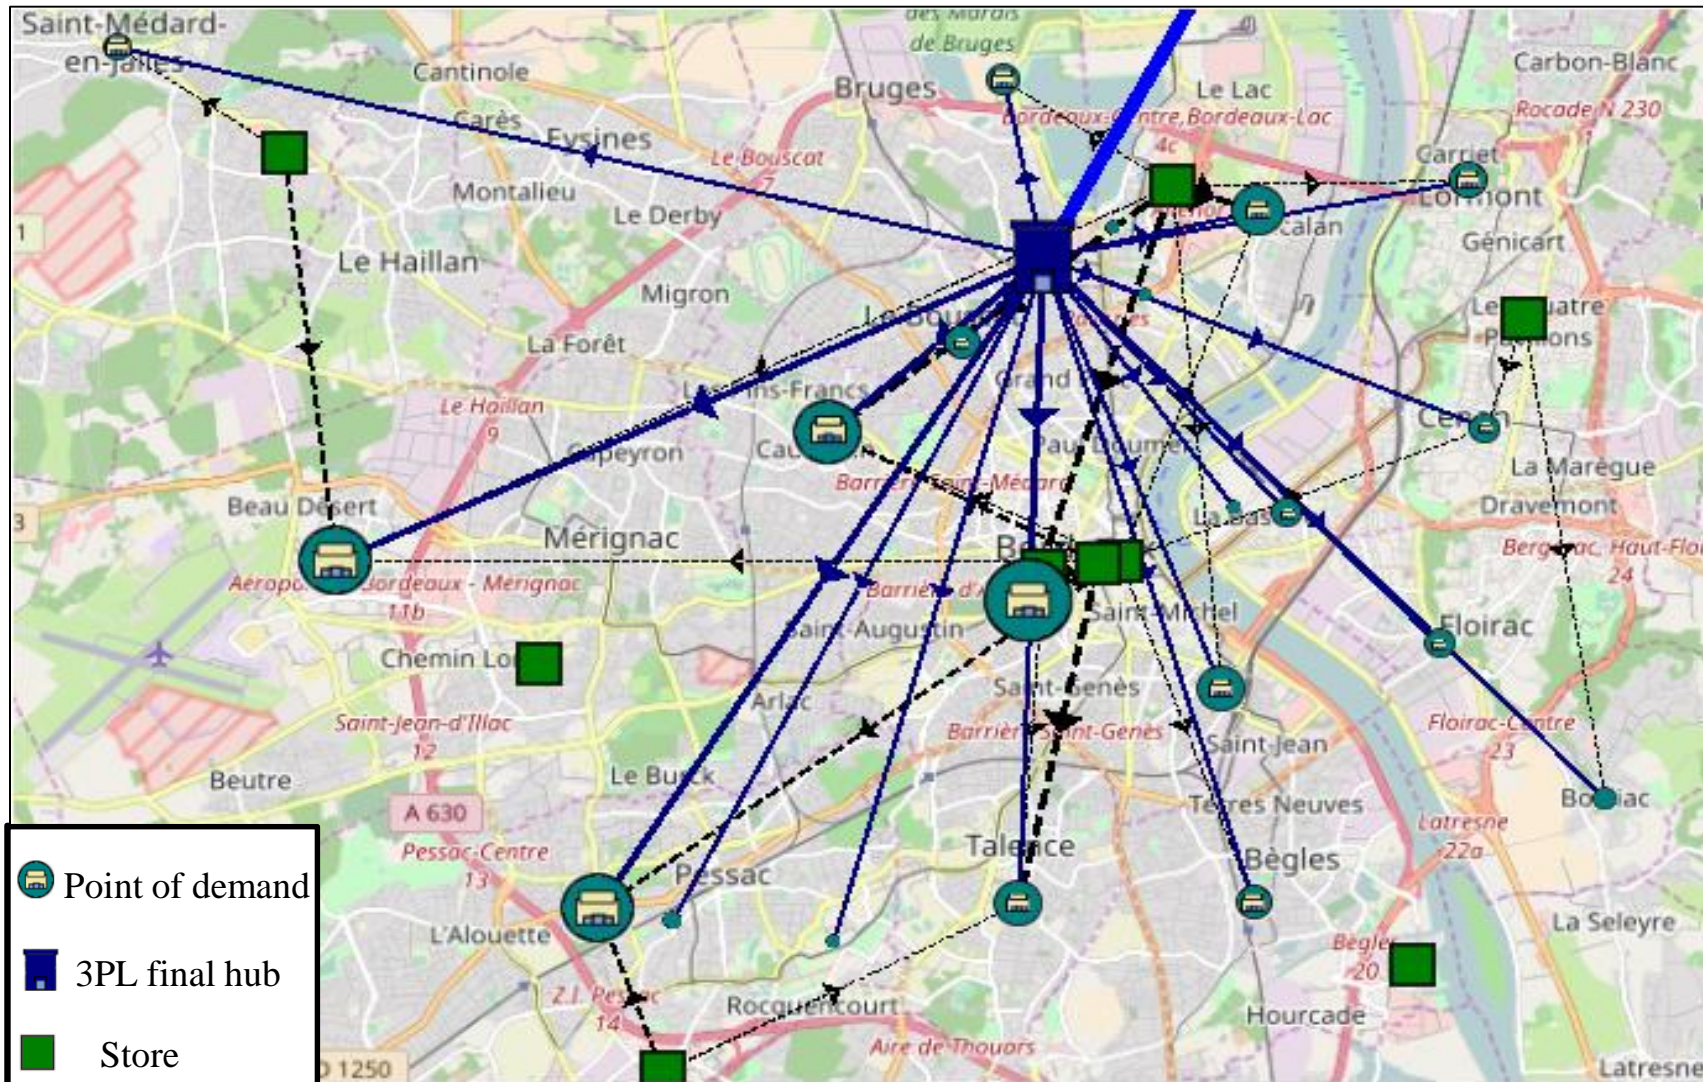

If the online order **could be met** from multiple stores, then it is shipped from the most convenient one.

- $o_d^{t,DT}$ : Online order placed from point of demand  $d$ , at time  $t$  with a required delivery time  $DT$ .
- $DT$ : Delivery time required for the online order  $o_d^{t,DT}$ .
- $DT_w^t$ : Delivery time provided by the warehouse  $w$  for servicing point of demand  $d$  at time  $t$ .
- $DT_s^t$ : Delivery time provided by the store  $s$  for servicing point of demand  $d$  at time  $t$  (Exceptions such as working time schedule (normal days of working/weekends) were considered.)

## Scenario 1 : Ship from Store

Flow of orders shipped directly from the warehouse

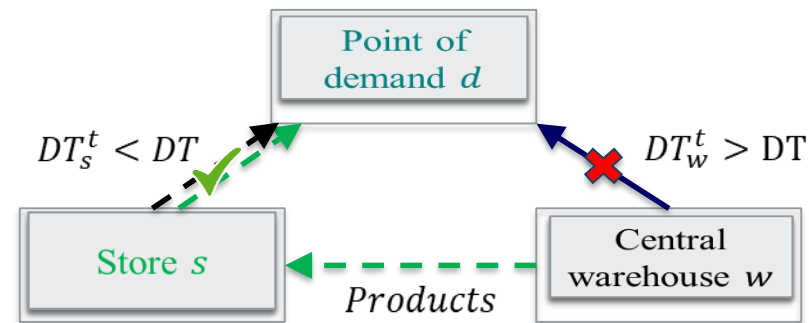

Flow of orders shipped from the store using existing inventory

## Distribution design models

### Scenario 2: Ship from store using existing and advanced inventory

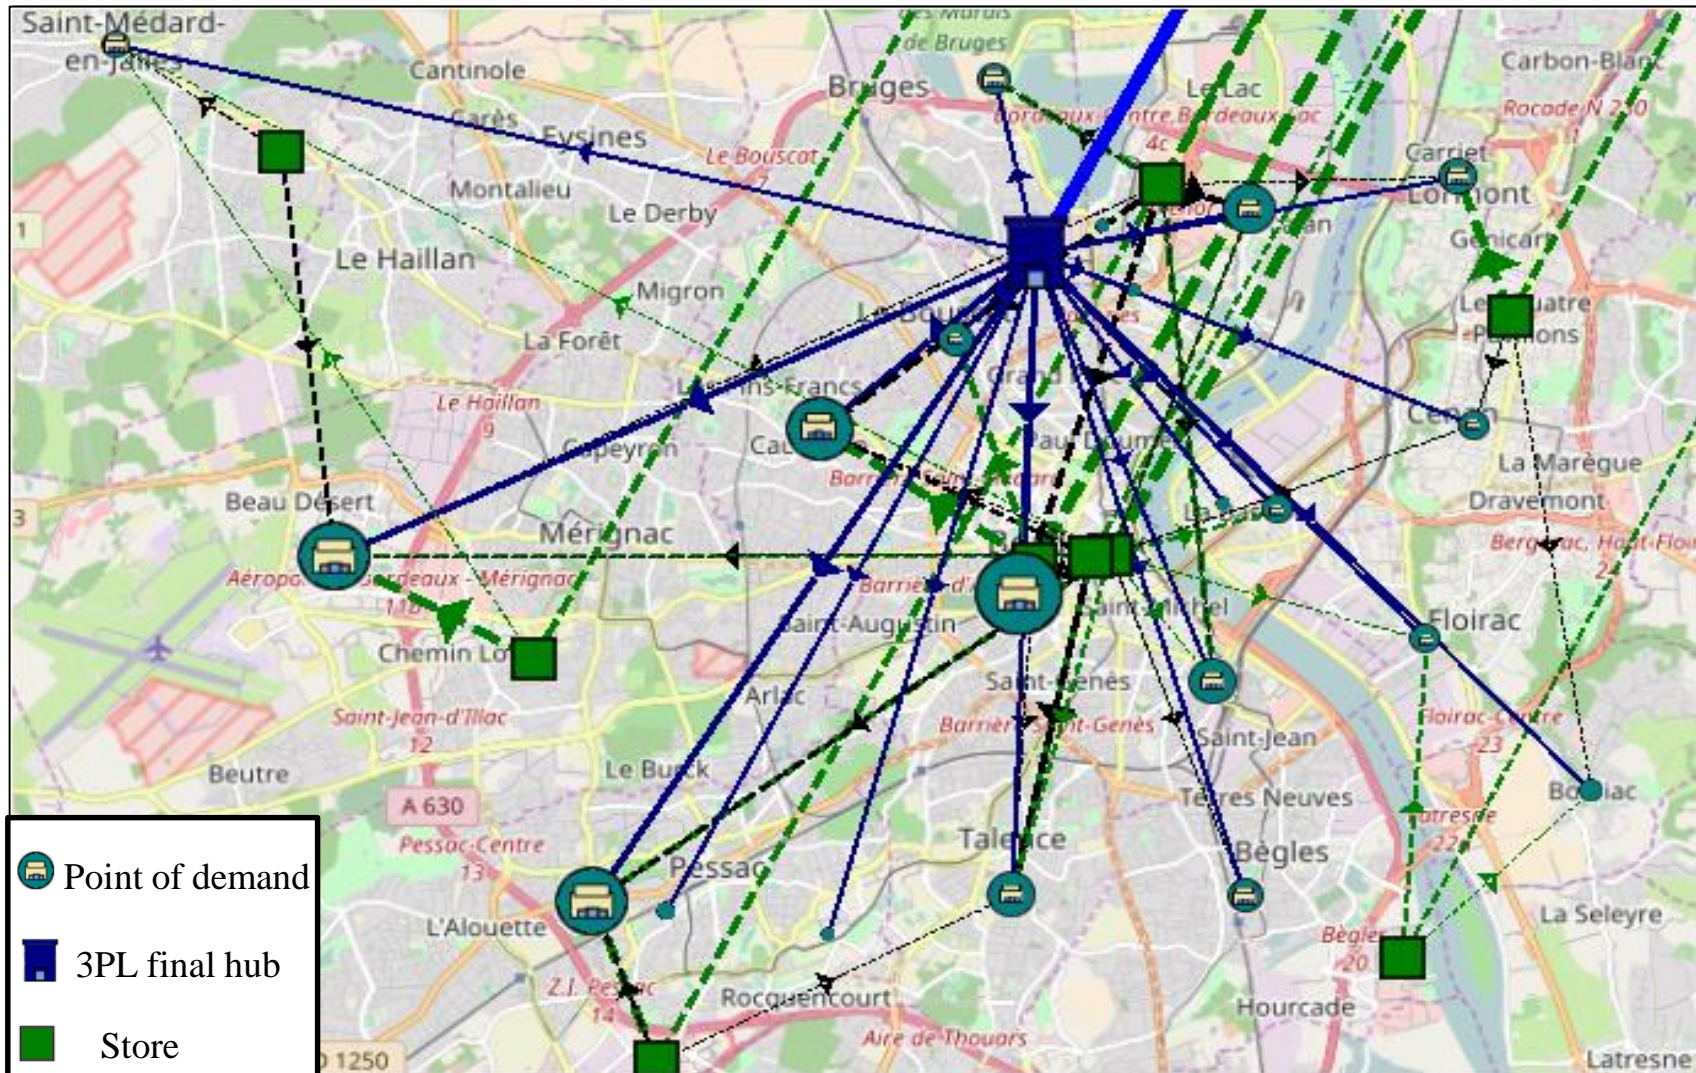

In addition to the first scenario option, if the online order belongs to the **fast moving high-quantity** and **doesn't exist in any store**, then we **anticipate/forecast** its optimal location in stores.

- $o_d^{t,DT}$ : Online order placed from point of demand  $d$ , at time  $t$  with a required delivery time  $DT$ .
- $DT$ : Delivery time required for the online order  $o_d^{t,DT}$ .
- $DT_w^t$ : Delivery time provided by the warehouse  $w$  for servicing point of demand  $d$  at time  $t$ .
- $DT_s^t$ : Delivery time provided by the store  $s$  for servicing point of demand  $d$  at time  $t$  (Exceptions such as working time schedule (normal days of working/weekends) were considered.)

## Scenario 2: Advanced inventory & Ship from stores

— Flow of orders shipped directly from the warehouse

- - - Flow of orders shipped from the store using existing inventory

- - - Flow of orders shipped from the store using advanced inventory

## Distribution design models

### Scenario 3: Hyperconnected distribution network using existing and advanced inventory

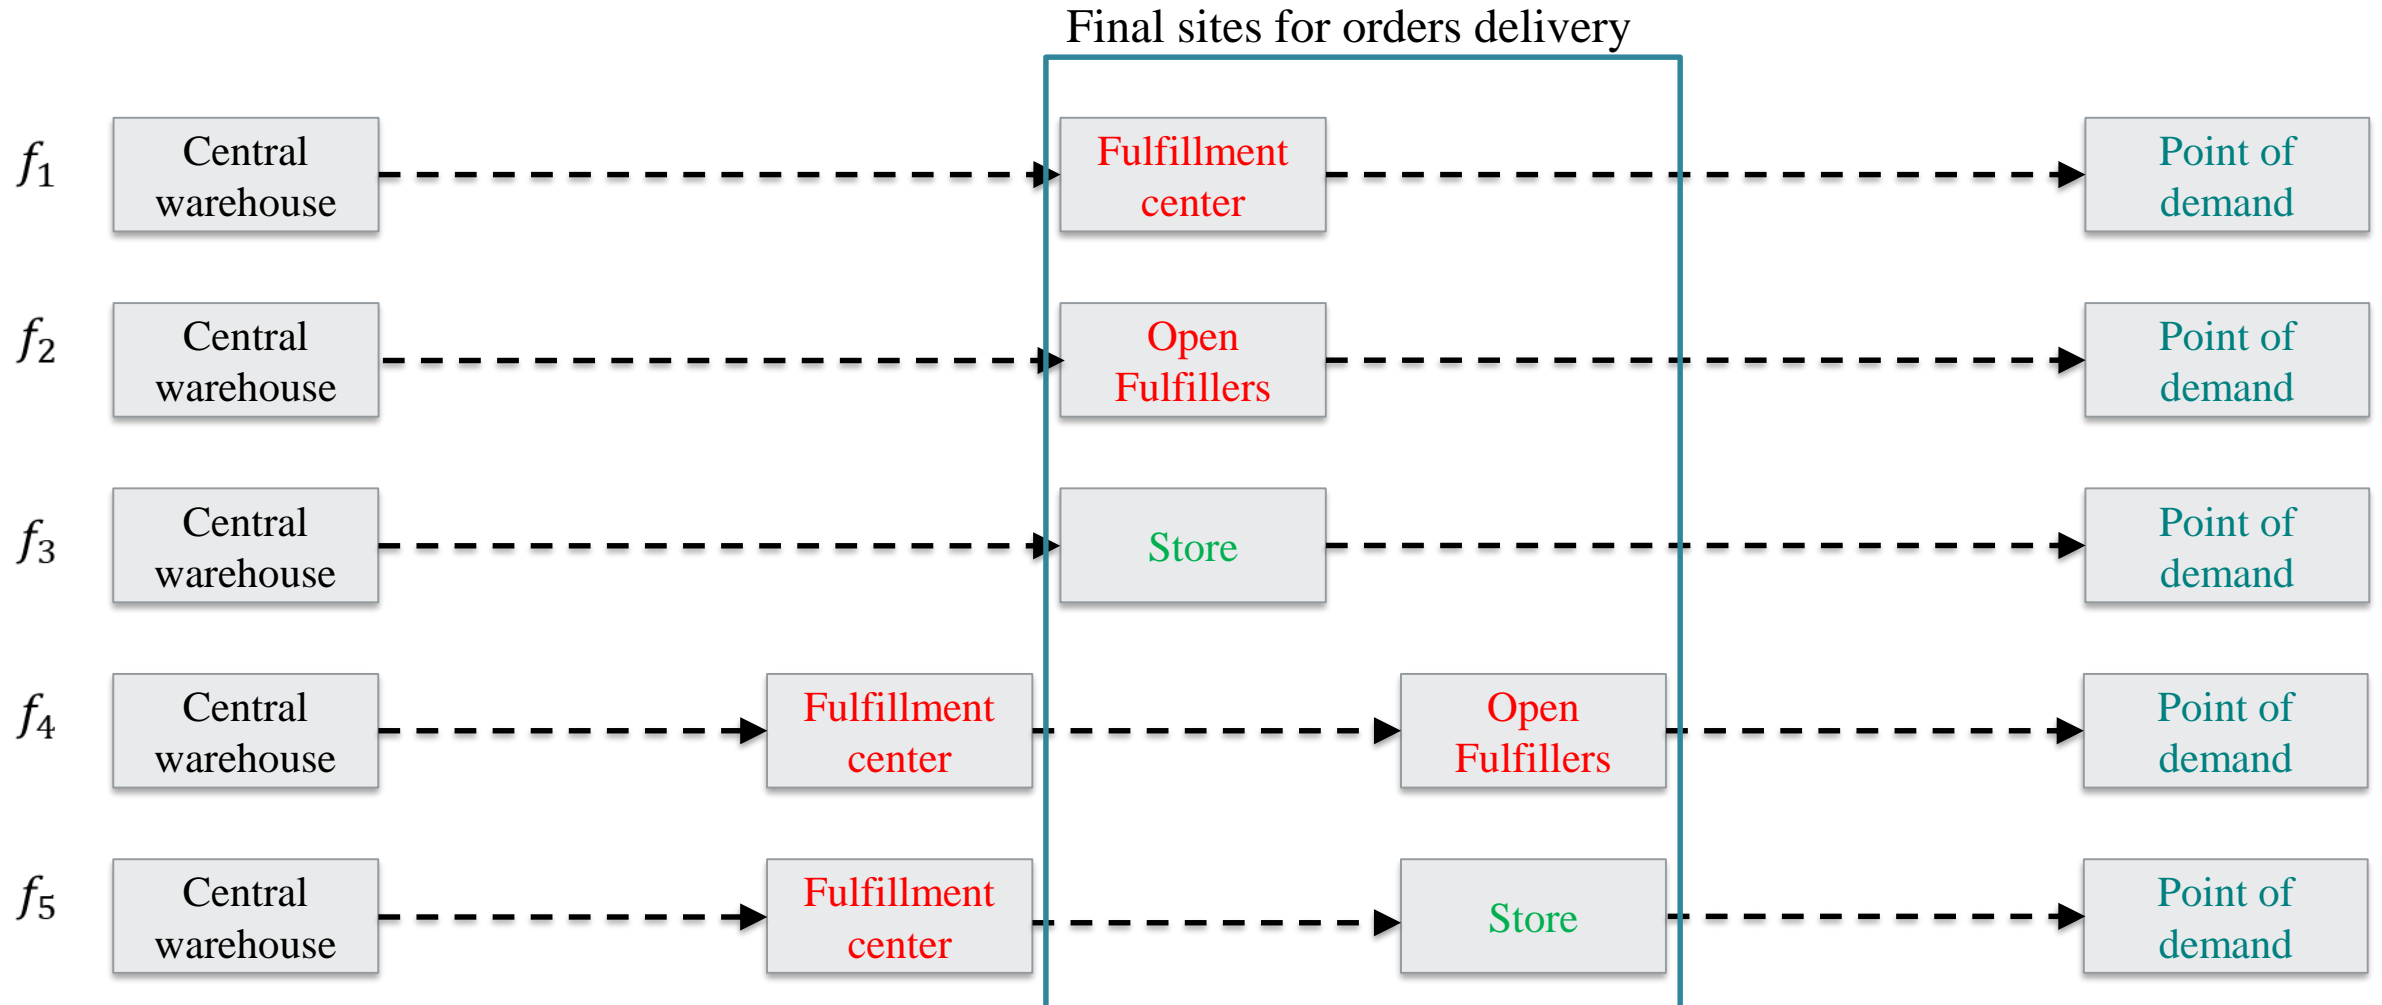

The business imparts a part of its operations to a **fulfillment service provider (FSP)**. The FSP allows to cross-dock the business products in **open Hubs**, spread over the region and fed from the business central warehouse. The **advanced** inventory is based on **forecasted deployment** of products in all sites.

- $o_d^{t,DT}$ : Online order placed from point of demand  $d$ , at time  $t$  with a required delivery time  $DT$ .
  - $DT$ : Delivery time required for the online order  $o_d^{t,DT}$ .
  - $DT_w^t$ : Delivery time provided by the warehouse  $w$  for servicing point of demand  $d$  at time  $t$ .
  - $DT_f^t$ : Delivery time provided when selecting the facility  $f$  for servicing point of demand  $d$  at time  $t$
- (Exceptions such as working time schedule (normal days of working/weekends) were considered.)

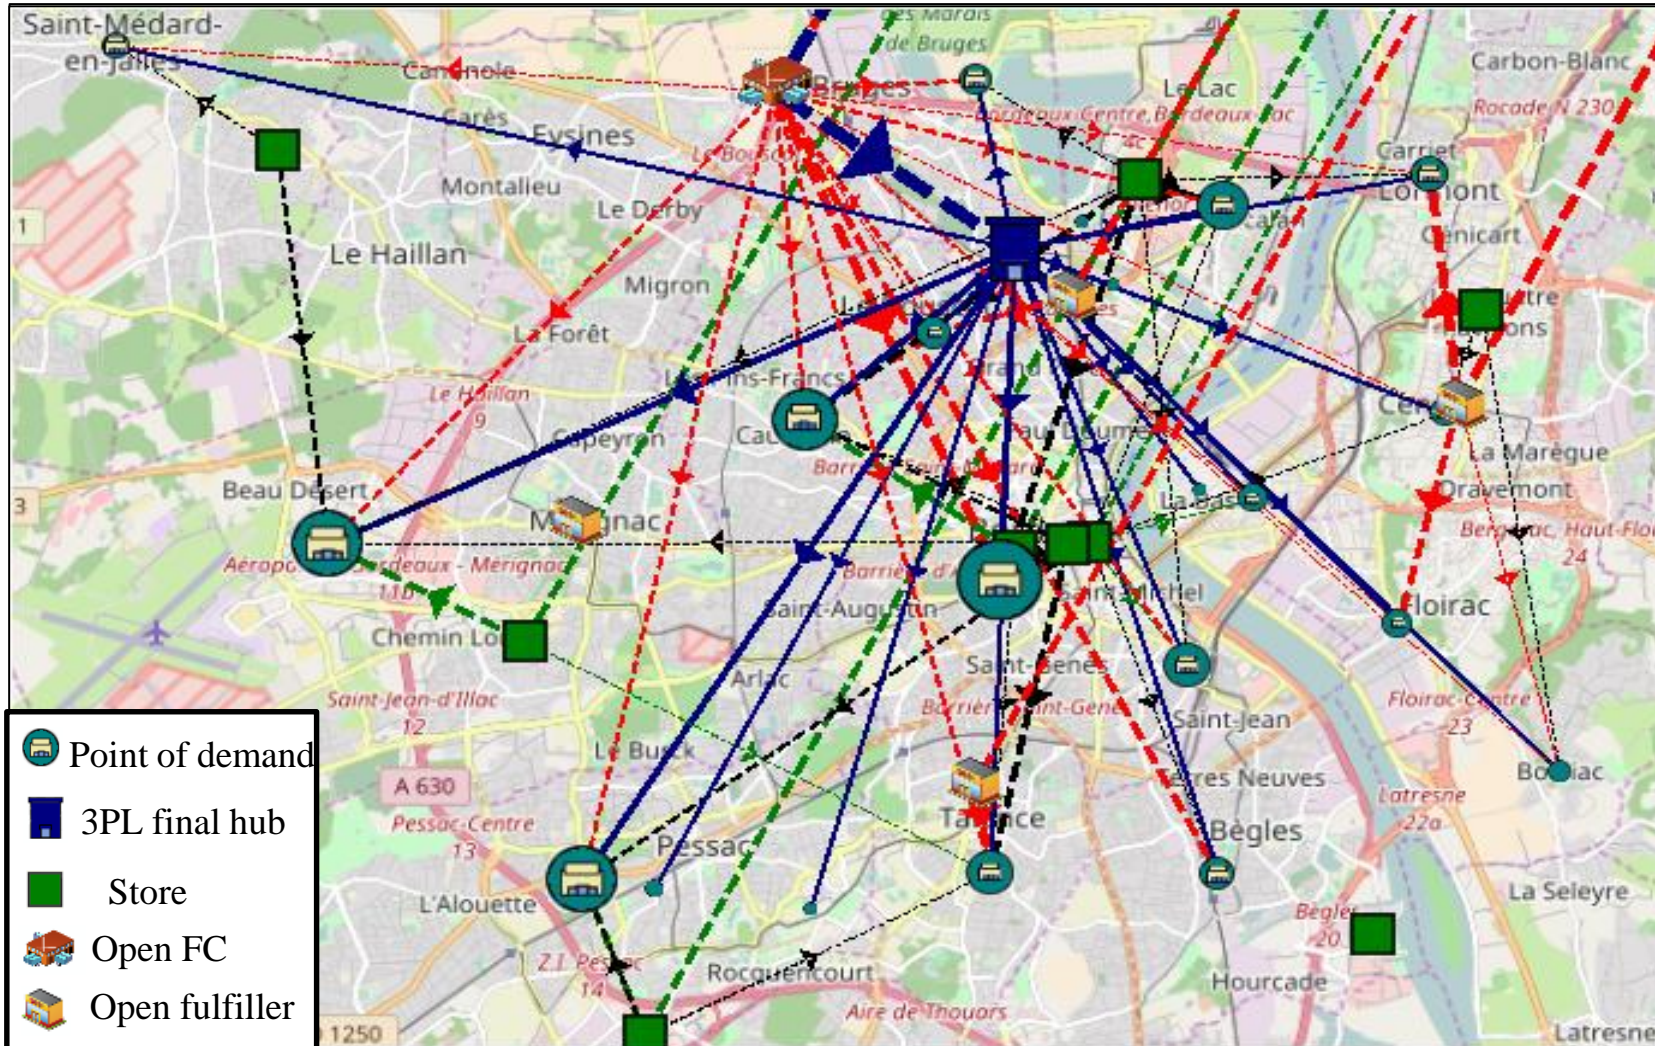

## Scenario 3 : Fulfillment centers-based distribution

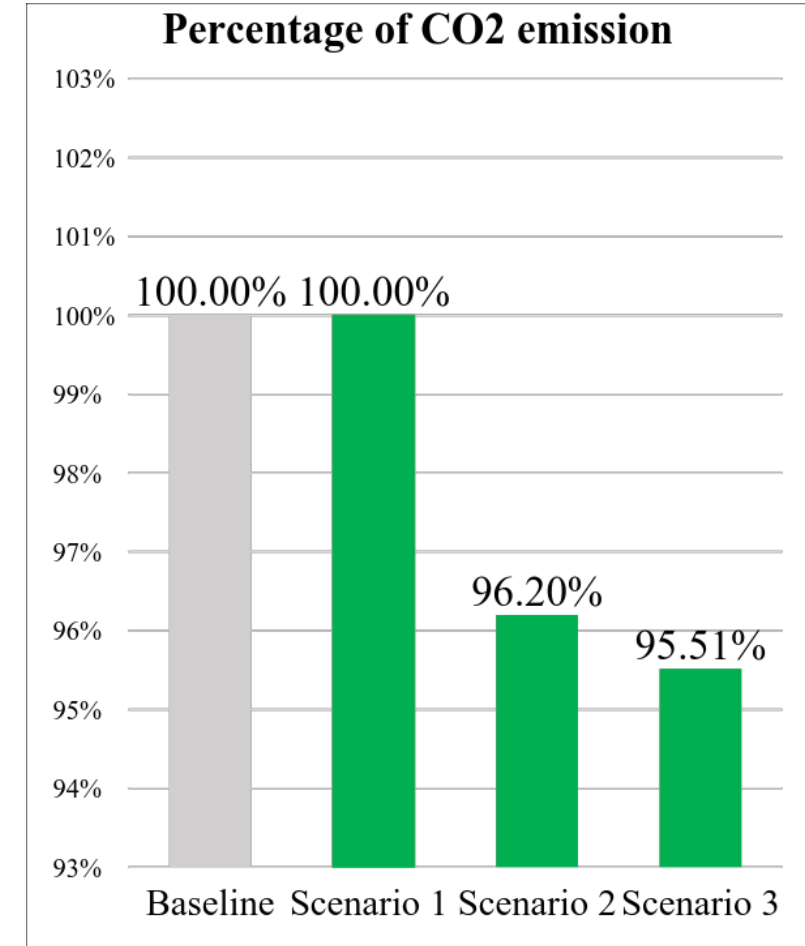

## Scenario 3 : Fulfillment centers-based distribution

- Flow of orders shipped directly from the warehouse
- Flow of orders shipped from the store using existing inventory
- Flow of orders shipped from the fulfillment center
- Flow of orders shipped from the store using advanced inventory
- Flow of orders shipped from the openly FC/fulfillers using advanced inventory

## Results

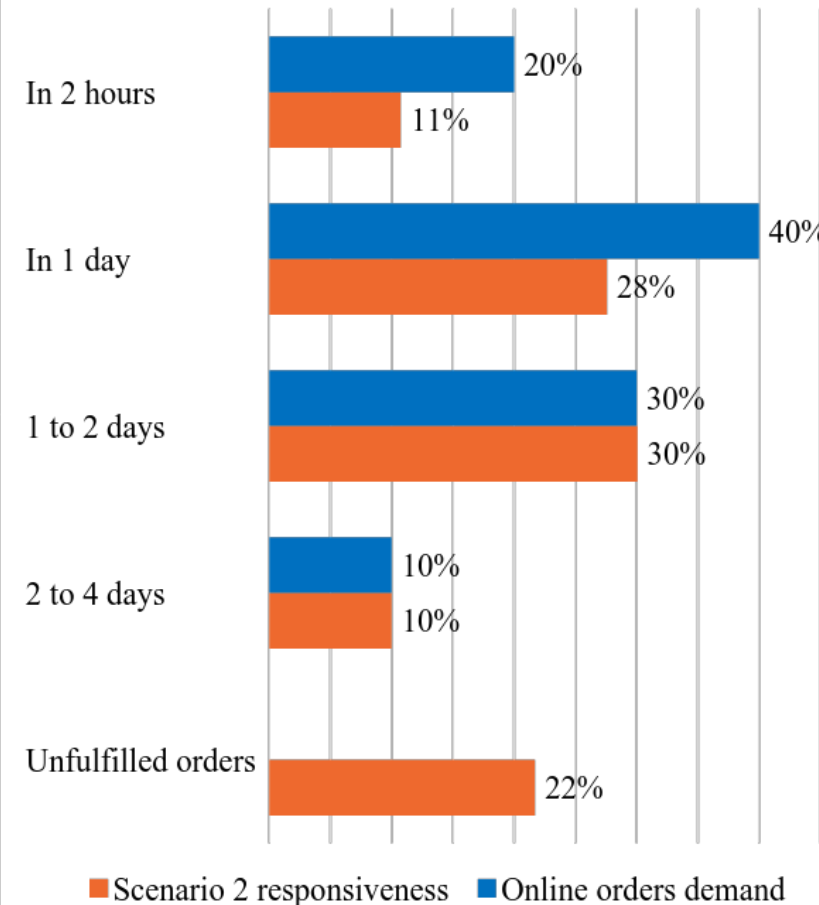

# Results: Impact of Hyperconnected distribution on service level

**Service Level: Scenario 1 responsiveness to monthly orders demand**

**Service Level: Scenario 2 responsiveness to monthly orders demand**

**Service Level: Scenario 3 responsiveness to monthly orders demand**

## Conclusion & Future Work

- The percentage of fulfilled online orders increased by **22.2%** when the retailer stores were exploited; and by **44%** in a hyperconnected distribution network.
- The CO<sub>2</sub> gas emission of total hyperconnected network flows decreased by **220 Kg** in one month due to improvement of trucks fill rate.
- Scenario 1: we are exploring the idea to add pick-up and delivery lockers at stores
- Scenario 2 : we are working on Machine Learning algorithms to improve the forecasts
- Scenario 3 : we need to estimate the opening/warehousing cost of the fulfillment center
- A Simulation model is under development to strength the proof-of-concept

**Thank you for your attention**

# APPENDIX

## Upstream Transportation Cost Estimation

The **trinomial formulation of the cost price** makes it possible to calculate simply the cost of a Transport using three terms:

- **Kilometer cost term:** encompasses fuel, tires, maintenance-repairs and tolls costs
- **Hourly cost term:** includes the driver's salary and remuneration
- **Daily cost term:** covers the total indirect structural costs, Insurance and axle tax

**Transport operation cost =**

**Kilometric cost \* total number of kilometers traveled for the transport operation**

**+Hourly cost \* number of hours of service required by the operation**

**+Daily cost \* number of days of use of the vehicle for the transport operation**

**Transport operation cost (A → B) =**

***Kilometric cost \* distance(A → B)***

**+Hourly cost \*  $\frac{\text{distance}(A \rightarrow B)}{\text{speed}}$**

**+Daily cost \*  $\frac{\text{distance}(A \rightarrow B)}{\text{speed} * \text{number of working hours}}$**

**Online order transport cost (A → B) =  $\frac{\text{Transport operation cost (A→B)}}{\text{Total freight(A→B)}} * \text{Online order weight}$**

## Upstream Transportation Cost Estimation

Advanced store

+ Additional weight per delivery

$$\text{Online order transport cost (A} \rightarrow \text{B)} = \frac{\text{Transport operation cost (A} \rightarrow \text{B)}}{\text{Total freight(A} \rightarrow \text{B)} + \text{Additional weight(A} \rightarrow \text{B)}} * \text{Online order weight}$$

## Upstream CO2 Emission Estimation

Online order CO2 emission = CO2 factor emission \* distance \* Order weight

# Potential of a cross-company reusable modular secondary packaging system in E2E FMCG chains

Yanyan YANG, Eric BALLOT  
4th IPIC 2017, Graz

# 1. Context

**Packaging:** technology of enclosing and protecting products for distribution, storage, sale and use.

**Logistics units (Units load):** combines primary products into single shipping “units” to facilitate transport, handling and storage that represent 12-15% of retail sales price.

Primary packaging (sales unit): package to final consumers, e.g., . bottles, bags etc.

## Scope of study

Secondary unit load: basic handling unit consisting a group of sales units, e.g., trays, crates, boxes etc.

Tertiary unit load: combines secondary unit loads or sales units, e.g., pallets, dollies, roll cages etc.

Fig 1. Three level of packaging

# 1. Context

**Challenge ahead:** Different solutions by different actors across the chain.

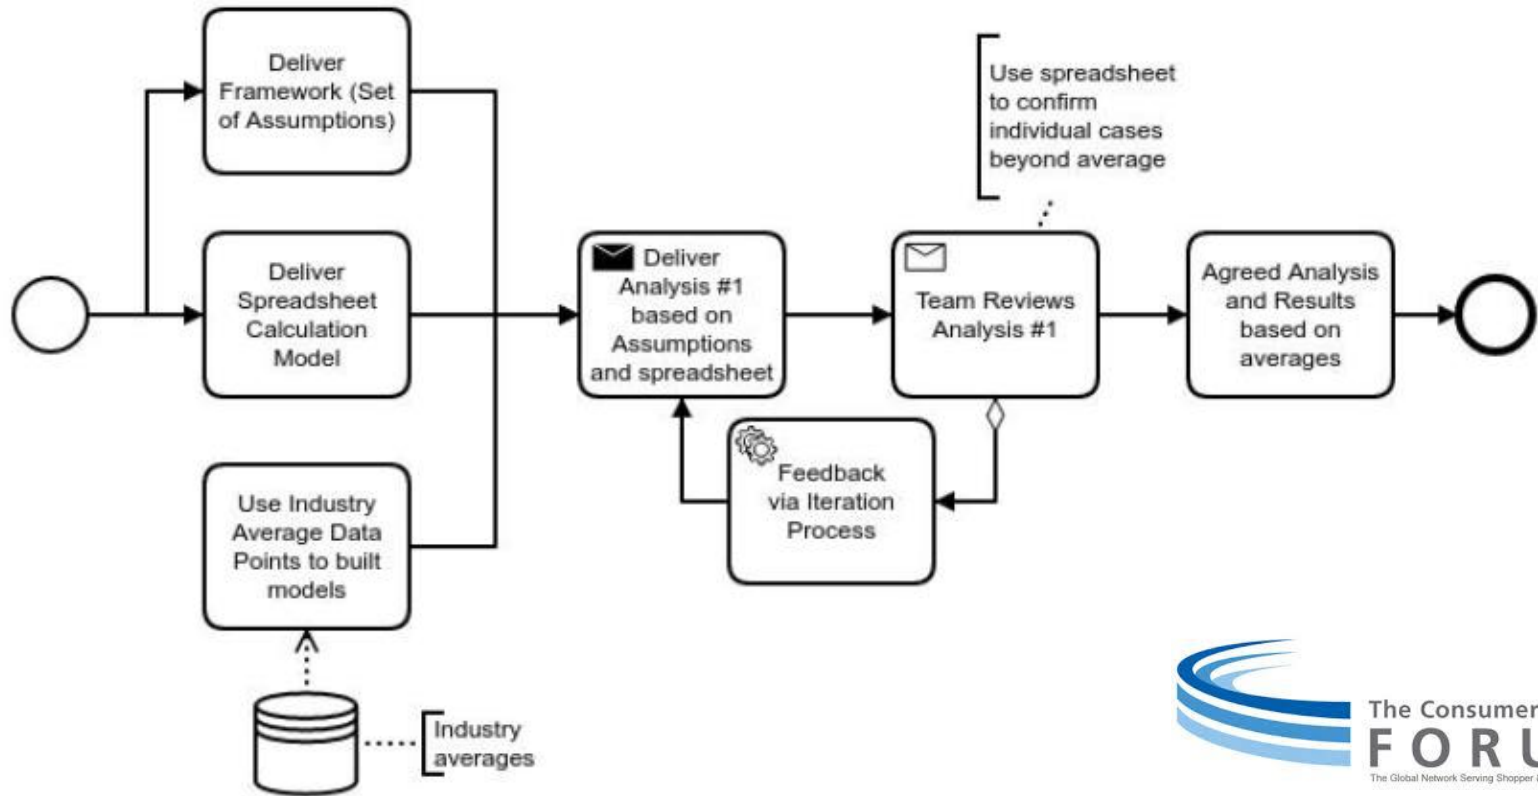

## **Global inefficiencies:**

- 1) Poor fill level of packaging units and transportation means, e.g., averagely 42,6% average utilisation of trucks and containers at departure.
- 2) Poor storage space utilisation.
- 3) Negative impacts on environmental footprint, e.g., increased waste, CO2 emission.
- 4) Inefficiencies in handling, e.g., re-package of products to feed into new systems.

# 2. Objective and methodology

**Objective:** to provide a generic modular solution across categories and supply chain levels globally.

**Method:** global assessment of implementing a small set of standardized modular boxes throughout a reduced set of typical FMCG supply chains.

# 3. Other projects related

Project RTI( Reusable Transport Items): to define a practice approach to establish a cross-company returnable packaging system in the retail supply.

Project Orange Box: to identify quick wins and profit return of investment of standard containers across the chain with distributors.

Project NMLU: to develop and prototype New Modular Load Units (NMLUs), especially for the use of multimodal logistic clusters.

**Our initiative:** To quantitatively study the major differences of using modular boxes compared to actual solutions in end-to-end FMCG chains, eventually the global benefits and frontiers of modularization in secondary packaging.

# 4. Example of possible scenarios - typical FMCG chains

1

**Fast moving  
High volume**

Manufacturer's  
warehouse  
(WH)

Retailer's  
Distribution  
centre (RDC)

2

**Fast moving  
High volume**

3

**Fast moving  
Small volume**

4

**Slow moving  
Small volume**

# 5. Assumptions and model

---

## Assumptions

1. A set of four modular boxes by (Meller, Lin, and Ellis 2012): Sizes =  $\{\{600 \times 400 \times 240\}, \{400 \times 300 \times 240\}, \{600 \times 400 \times 120\}, \{400 \times 300 \times 120\}\}$  in mm
2. Recycling or disposal of packaging material: close loop (shipment back to origin) and open loop (shipment to nearest consolidation centre).
3. A product could be packed in boxes of different sizes according to the demand.
4. A modular box can contain a single type of product or different products
5. Average shipping unit height and weight will be used instead of actual loads.

....

# 5. Assumptions and model

## **Objective of calculation model: analysis of following key differences**

1. Asset utilization (saturation of means)
  - a) Boxes level
  - b) Handling unit level
  - c) Transportation means level
2. Handling productivity
  - a) Loading and unloading at handling unit level
  - b) Breakdown, when boxes are manipulated from one pallet to another
  - c) Picking when a product is manipulated from one box to another
3. Circulation/Recycling of RICs or the support
  - a) Re-utilization: close loop and open loop (wit)
  - b) Disposal & supply of actual cardboard boxes

## **Objective for the pilots:**

1. Quality : Does the switch from a dedicated cardboard to a plastic box change quality issues (contamination, break ratio, damage ratio, etc)?
2. Sustainability : product waste, means fill rate, raw material consumption, water

# 5. Assumptions and model – calculation model

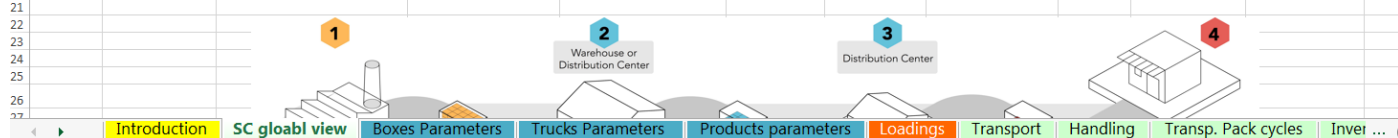

## Inputs:

- Distribution flows
- Information of products delivered (size, price, characteristics such as slow-mover or fast mover).
- Information of supports, packaging, and transportation (size, price etc).
- All cost settings: transportation cost, recycling cost, handling cost, etc.

## Expected results:

1. Key differences such as asset utilization across the chain.
2. Average costs: transportation costs per item delivered, handling costs per item delivered, recycling or disposal costs, stocking cost per item delivered.

	A	B	C	D	E	F	G	H	I	J	K
2		<b>Input</b>	One cardboard box, 4 modular boxes, 1 product								
3			Transportation cost	Euro semi-trailer truck	Variable travel cost	1,2	€/km				
4					Fixed cost		€				
5				Duty Vehicle	Variable travel cost	1,7	€/km				
6					Fixed cost	20	€				
7											
8			Load/unload pallet to/from trucks	Cost/unit	3	€/load					
9				Fixed and extra cost	10	€/truckload					
10											
11			Load/unload boxes to/from pallets	Handling cost per box	0,2	€/box					
12				Fixed cost per pallet	3	€/support					
13											
14			Pack/repack cost per product unit	Handling cost per product unit	0,1	€/product					
15											
16											
17			Recycling	Modular box reconditioning cost per box	0,5	€/box					
18				Cardboard box disposal cost	3	€/kg					
19											
20			<b>Actual supply chain with cardboard box</b>								
21											
22

# 6. Conclusions and next steps – main levers

Via:

- Significantly reduced transportation costs through standardisation of boxes, e.g., open loop for recycling modular boxes vs. close loop for disposing current packaging units.
- Open loop: shipment to consolidation centre via standardisation.

Via:

- Less non-value adding handling operations, e.g., pallets breakdowns, repackaging.
- Automation handling system through standardisation.
- Adapted quantity directly to shelves.
- Avoid extra manipulation

**Key Drivers**

- High storage space utilisation
- High Box fill rates
- High fill rates of transportation

Via:

- Reduced lead times, especially for slow moving products and small quantities.
- Improved shelf availability

Via:

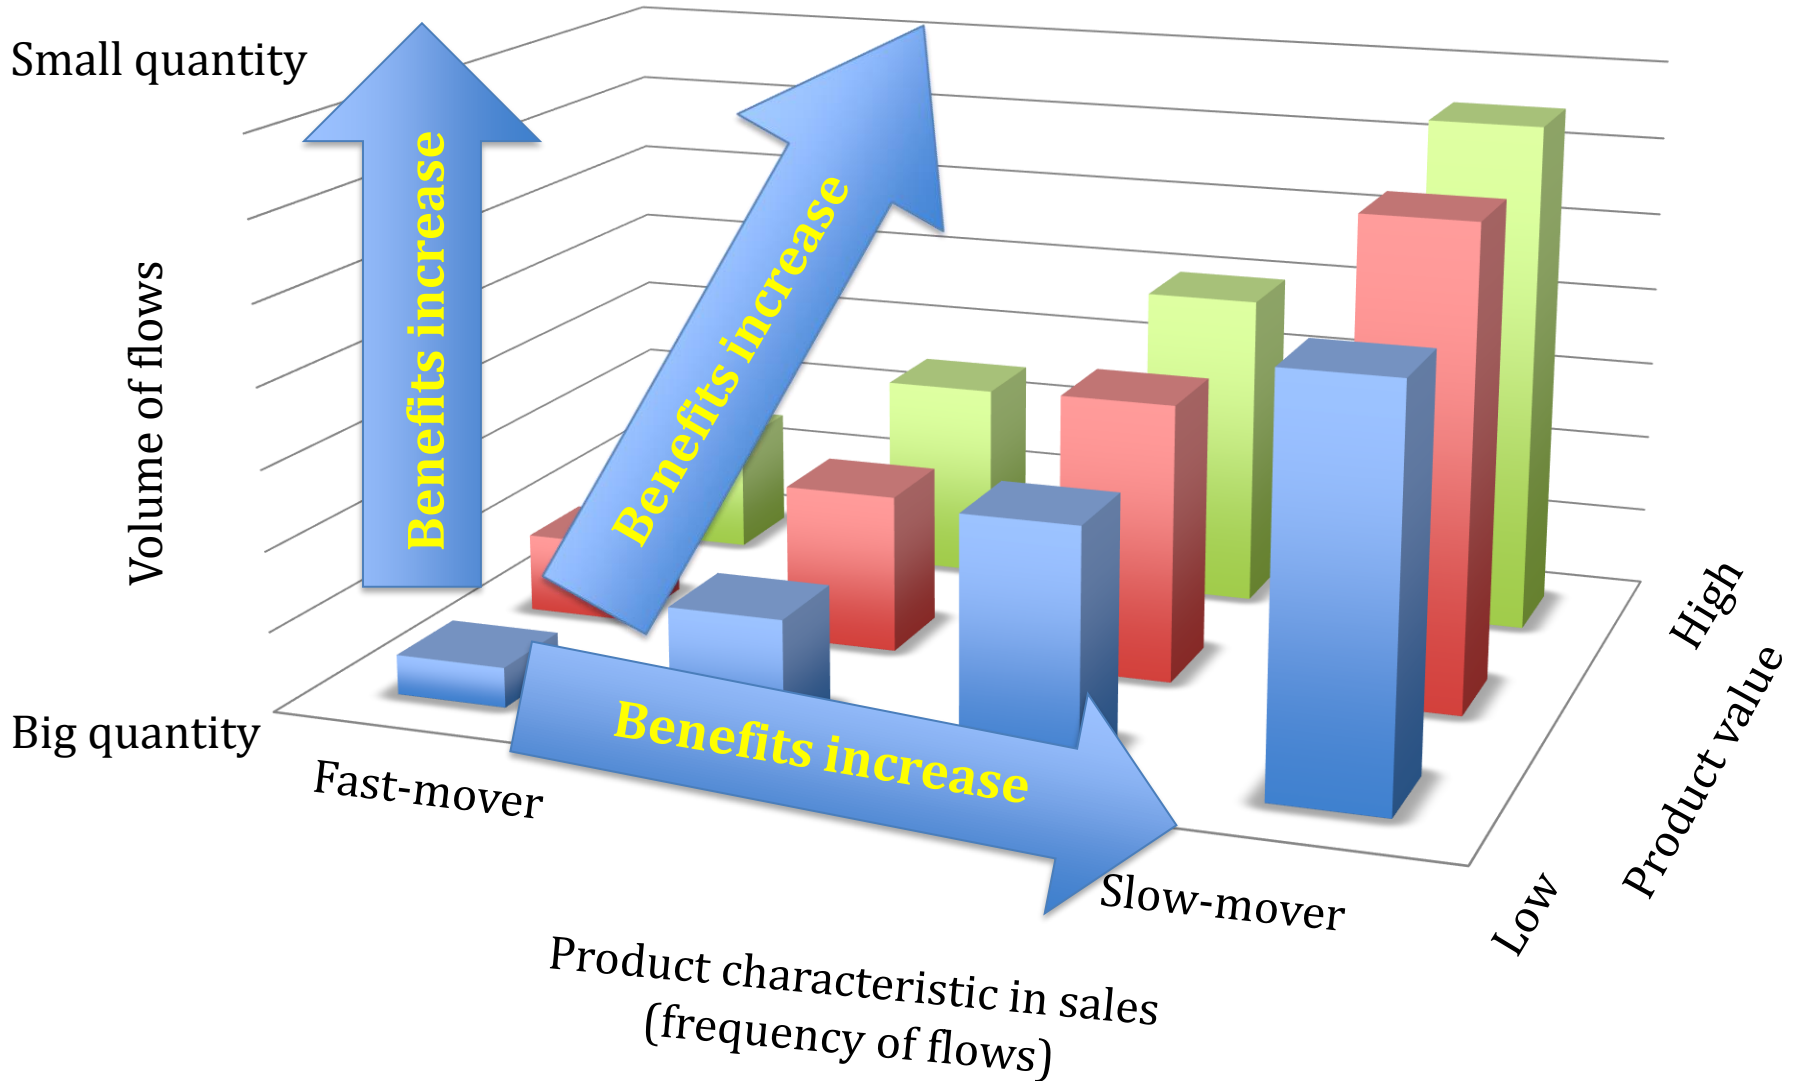

- Less void of space utilisation through modularity
- Stackability of modular boxes
- Capability of containing different products in the same box.

Via:

- Reduced damage through automatic handling.

# 6. Conclusions and next steps

## Qualitative analyse of potential benefits:

# 6. Conclusions and next steps

---

## **What is done:**

- ✓ A calculation model developed in the Excel and need to be further applied in France or European horizon.
- ✓ Qualitative analysis is taken out to study the potential drivers of modular boxes.

## **Next steps:**

- ✓ Encourage more partners to join to have a vision of the whole chain.
- ✓ Case studies of different categories of product from different industrial partners as to demonstrate the qualitative results.
